

# TikTok System Design

TikTok is a video-sharing platform between users. Uploading, view video and scroll up to change video.

## Functional Requirements

1. Upload Videos [MaxLength: 1 min, Text(caption)]
2. Follow users
3. Favorite Video

## Non Functional Requirements:

1. High Availability (5 9s or 99.999%)
2. Low Latency
3. Scale

## Estimations:

Say we have 1 million active users (AU) per day and on average a user uploads, 2 videos per day.

Videos: 5MB for 1 min

Total Storage per AU per day:  $5\text{MB} * 2 = 10\text{MB/AU/day}$

User MetaData: 1KB/AU/day

## DataBase:

## Video Table

|                |
|----------------|
| user_id: uuid  |
| video_id: uuid |
| video_url: url |
| meta: string   |

Video Table

## User Activity Table

|                        |
|------------------------|
| user_id: uuid          |
| video_id: fk(video_id) |
| following: fk(user_id) |

User Activity Table

## Services:

1. User App: Used to upload/watch videos.
2. CDN: We can put API servers behind some CDN as we have users globally. We can have regional databases behind CDN.
3. Load Balancer: Behind API servers in a region for scalability.
4. Upload Video Service
5. User Activity Service
6. View Feed Service: Fetch top 10 videos from cache(like Redis).
7. Cache Populator Service: Cron which populate the cache with say top 10 videos per user. Also, we can run this service on demand to fetch more videos say when a user viewed 5 out of 10 videos. It may use some machine learning algorithms to fetch videos.
8. View Feed Service: Fetch content from cache and serve to users
